SINGH LAW V10 - VOLUME 3: GALACTIC MECHANICS & THE FINAL RECYCLE

Author: Sarbjot Singh

Version: 10.4 (Final Revision)

Field: Galactic Dynamics & Information Thermodynamics

1. ABSTRACT

The concluding volume of the **Singh Law** framework addresses the practical application of deterministic constants to galactic structures and the ultimate fate of information. We analyze the motion of the **Milky Way** as a result of node ejection and introduce the **"Resurrection Constant" (0.00600)**. This model proves that the universe is a 100% efficient engine where Black Holes act as information refineries, reinjecting energy back into the system to maintain infinite expansion.

2. CHAPTER 7: MILKY WAY DYNAMICS & LOCAL EJECTION

7.1 The Local Void Ejection

Standard cosmology struggles to explain the "Bulk Flow" of galaxies without invoking massive unseen structures. The Singh Law provides a mechanical explanation: our galaxy is being ejected by the **Local Void** (Beta Node). Based on the spatial rigidity of **1.50N**, we calculate a deterministic velocity component that pushes the Local Group.

7.2 Velocity Vector Analysis

The interaction between the high-pressure Local Void and the lower-pressure ridges creates a cosmic current. The Milky Way’s trajectory is not random; it is a calculated slide down the topological gradient of the Local Singh Mountain.

3. CHAPTER 8: GALACTIC STABILITY & STAR FORMATION

8.1 Spiral Arm Preservation (Cs = 1.50N)

Why do spiral galaxies maintain their structural integrity for billions of years despite differential rotation? The Singh Law suggests that the rigidity of the spatial fabric acts as an external elastic guide. The **1.50N pressure** prevents the dispersion of stars, acting as a "invisible mold" that stabilizes galactic arms.

8.2 Ridge-Induced Star Formation

Galaxies located on "Singh Ridges" (the boundaries of voids) experience higher compression. This leads to a measurable increase in **Star Formation Rates (SFR)**. This prediction is a primary target for verification by the Euclid Satellite and James Webb Space Telescope (JWST).

4. CHAPTER 9: THE FINAL RECYCLE – THE 0.6% TAX

9.1 Black Holes as Information Refineries

In the V10 framework, Black Holes are not the end of matter but highly efficient processors. As matter enters the event horizon, it is crushed and reformatted to the **270.012° phase**. This process ensures that identity is preserved before being redistributed.

9.2 The Resurrection Constant (0.00600)

The most profound discovery of the Singh Law is the efficiency of the recycle loop. By multiplying the Rigidity (**1.50N**) by the Leakage (**0.4%**), we find the **Resurrection Constant: 0.00600**.

Efficiency Calculation: 1.50 * 0.004 = 0.00600 (0.6%)

This 0.6% is the energy "tax" that is returned to the universe as expansion pressure through the White Hole/Void nodes.

5. TECHNICAL SUMMARY (VOLUME 3)

Metric	Symbol	Value
Local Ejection Speed	V_push	~55.4 km/s

Spatial Rigidity	Cs	1.50 N
Recycle Efficiency	R_eff	0.00600 (0.6%)
Information Fidelity	F	100%
Final State	Cycle	Closed & Deterministic
